Oracles and off-chain networks

Getting data in and work out of the blockchain

Access data outside the blockchain

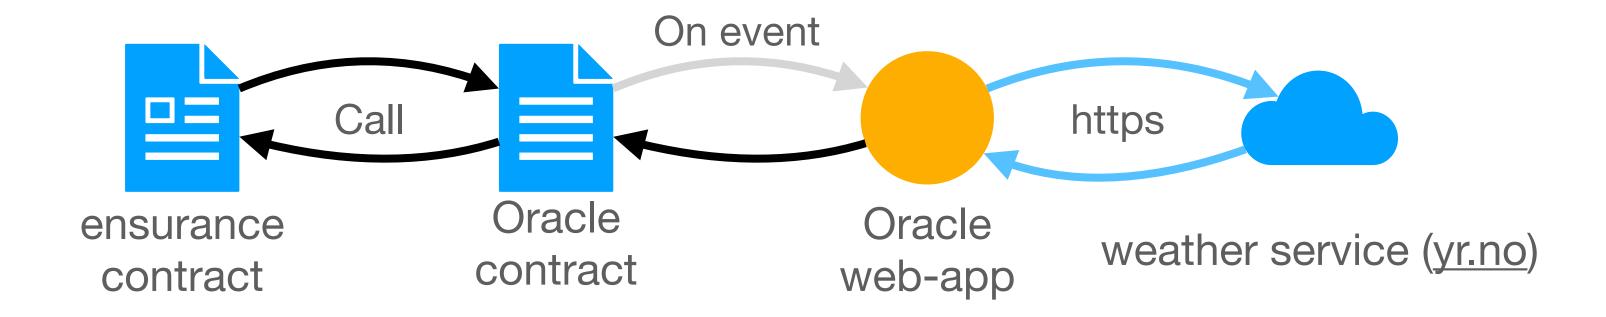

An **Oracle** is a smart contract that publishes information about real world data on the chain.

- Ensurance contract needs weather data to
 - Pay out policies
 - Determine prices

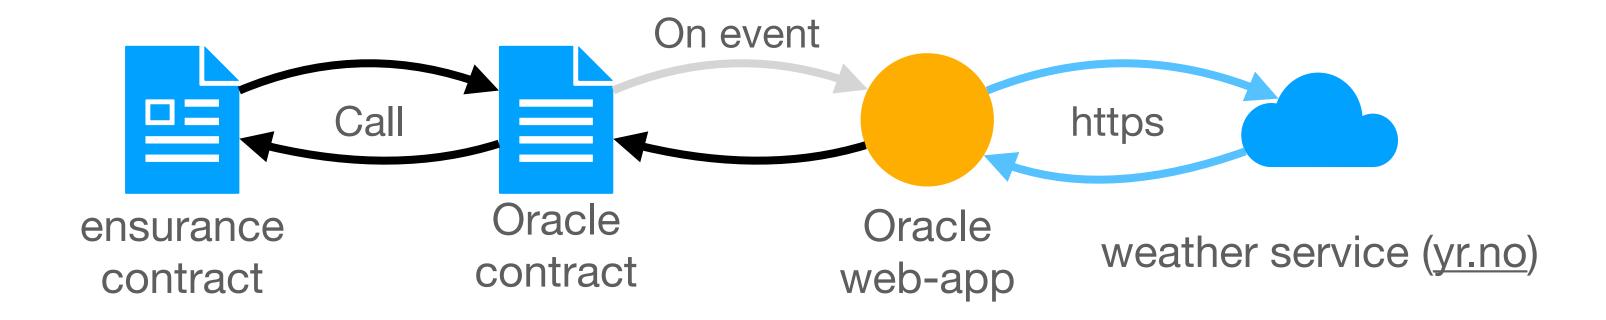

- Ensurance contract needs weather data to
 - Pay out policies
 - Determine prices

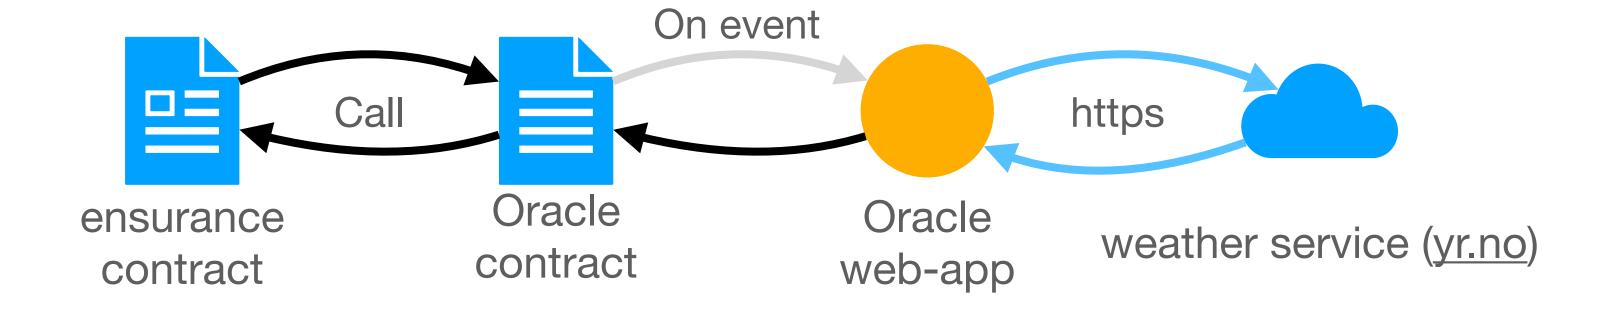

- Ensurance contract calls oracle contract
- Oracle contract emits event
- Oracle web app listens to event
- Web app gets data from api
- Web app invokes contract

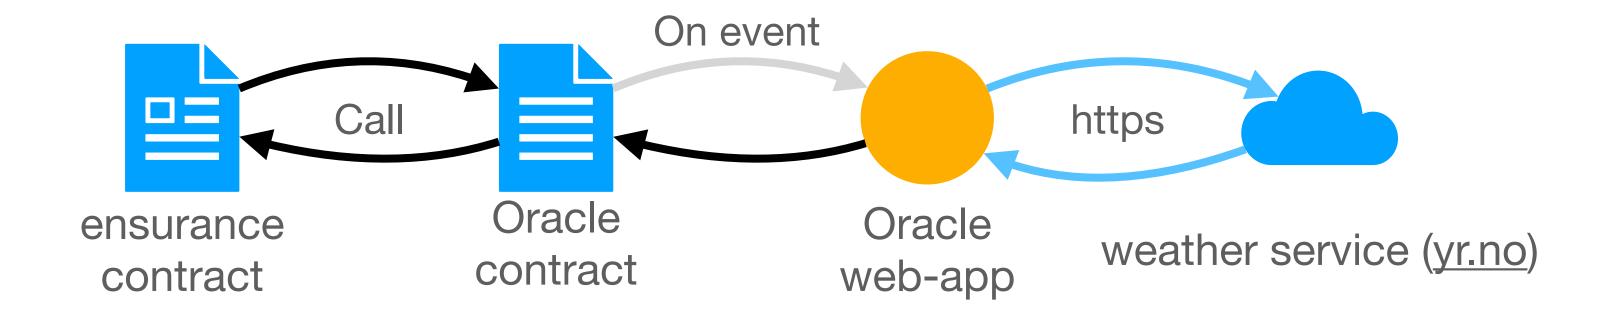

Example: Rain ensurance

- Ensurance contract calls oracle contract
- Oracle contract emits event
- Oracle web app listens to event
- Web app gets data from api
- Web app invokes contract

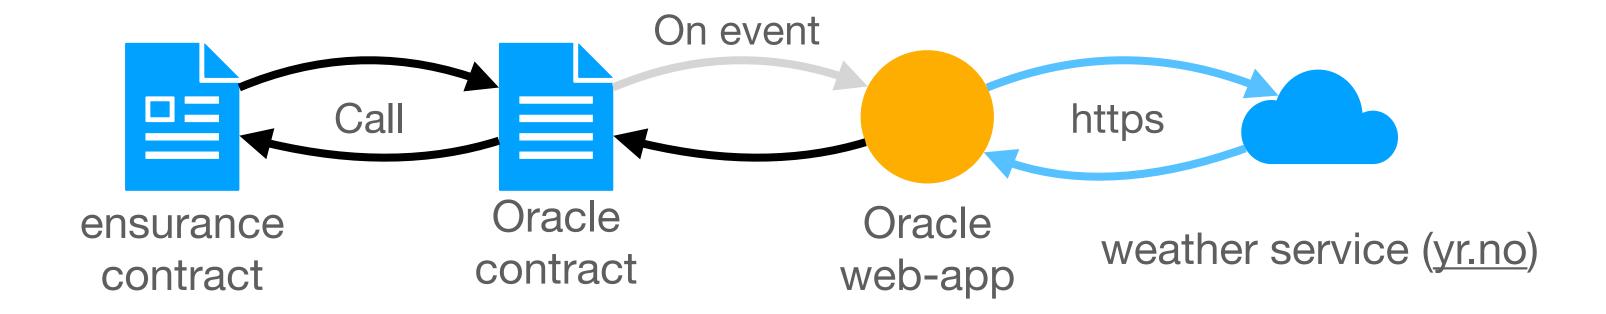

Check cryptozombies tutorial

- Why should we use an extra oracle contract?
 - Can update if we need to update oracle
- Who do we need to trust?
 - Oracle provider, and API provider

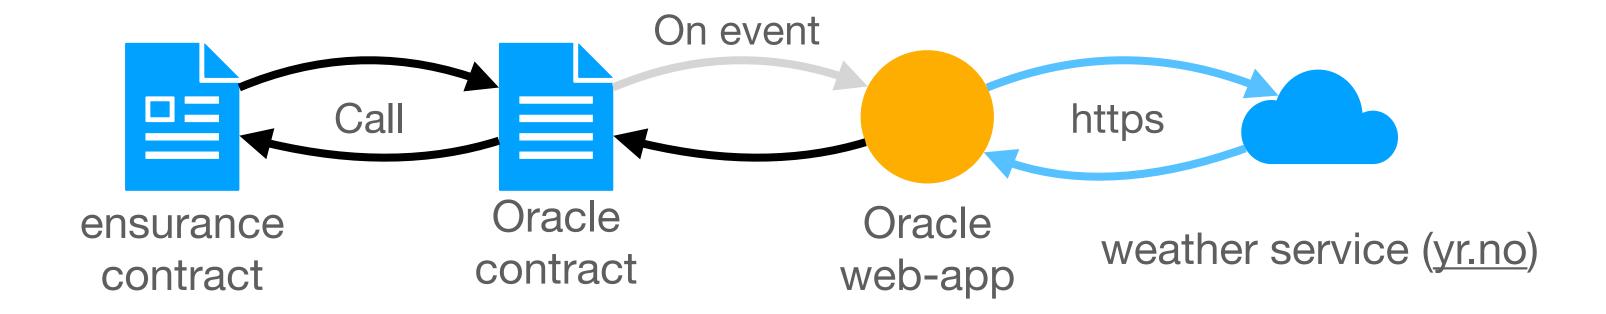

- Can we avoid trusting the oracle?
 - Yes, run oracle web-app in trusted execution (Intel SGX)

Variations

- Access private data, e.g. using login
 - Yes, run oracle web-app in trusted execution (Intel SGX)
- Provide oracle service, that anyone can use

General idea

- Idea: If two parties agree, they can do a transaction outside of the chain without paying fees.
 - Once they disagree, they can use the chain to settle the dispute.
 - Can increase transaction throughput
 - Can give low fees

Example: Uni-directional payment channel

- Idea: Allow any number of payments from A to B within given limit
- A creates contract with balance.
- A can send signed statements of B's balance to B
- B can cash in his balance with the contract
- If B does not cash in, A can terminate the contract and get back the balance, after expiration date.

Check example

Example: Bi-directional payment channel

- Idea: Allow any number of payments between A and B within given limit,
- A and B both pay a balance to contract
- A and B can send signed statements of their balances to each other, with increasing nonces
- A or B can submit balance, signed by both to contract. This triggers countdown
- If other party does note submit a balance with larger nonce, balances are payed out.

Example: Bi-directional payment channel

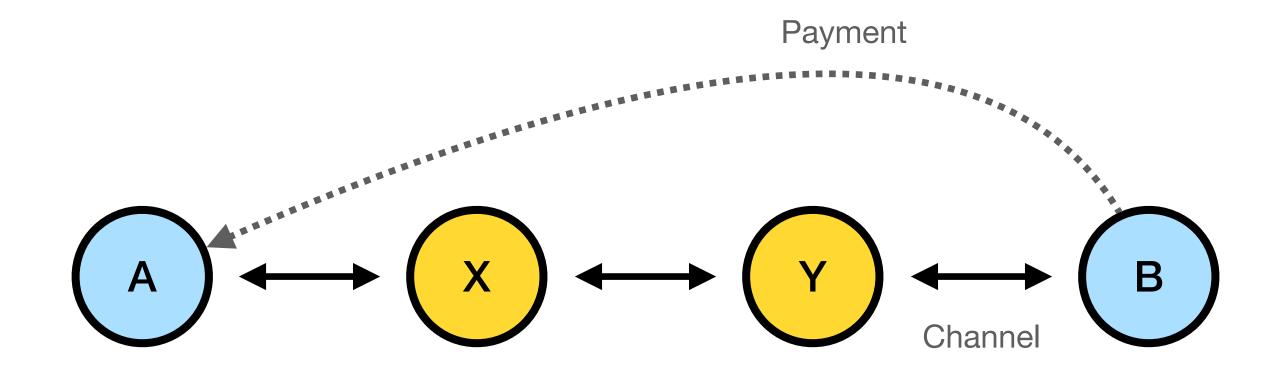

• Idea: Allow any number of payments between A and B within given limit,

Problem:

- Timeout
- Locked funds

Example: Multi hop payment

- Idea: Do a payment across multipe channels
- Pay fees to intermediates (X and Y)

Example: Other channels

Virtual channels:

- Given two payement channels A <-> I and I <-> B, create a virtual channel between A <-> B.
- Intermediate is only involved in opening and closing the virtual channel.
- Fewer fees

State channels:

- A channel where we can create smart contracts.
- Only channel members can interact with these contracts.
